

DP. Memoization

Fibonacci Sequence

```
int fib(int n){
  if(n <= 2){
    return 1;
  }
  else {
    return fib(n-1) + fib(n-2);
  }
}
```

```
const fib = (n) =>{
  if(n <= 2) return 1;
  return fib(n-1) + fib(n-2);
}
```

```
console.log(fib(7));
```

- Time complexity of fib function is $O(2^n)$

Time and space complexity of recursive function

- Analysing time complexity of a recursive function
-

```

1  const foo = (n) => {
2    if (n <= 1) return;
3    foo(n - 1);
4  };

```

$O(n)$ time
 $O(n)$ space

- Space complexity
 - when we analyse space complexity of recursive functions We should include any of the additional stack space
- for a function

```

void dib(int n){
  if(n <= 1){
    return;
  }
  dib(n-1);
  dib(n-1);
}

```

- Height is the distance between the root node and the furthest leaf node
- At every level we are calling the functions doubling the number of function calls
- for n levels our time complexity becomes $O(2^n)$

```

1  const dib = (n) => {
2    if (n <= 1) return;
3    dib(n - 1);
4    dib(n - 1);
5  };

```

$O(2^n)$ time

- At any point we use only 5 stacks for `dib(5)`
- Because after reaching five stack calls the functions returns
- it is only after return from left one we enter the right one.

```

1  const dib = (n) => {
2    if (n <= 1) return;
3    dib(n - 1);
4    dib(n - 1);
5  };

```

$O(2^n)$ time
 $O(n)$ space

- Time complexity is $O(n^2)$ and space complexity is $O(n)$

```

1  const lib = (n) => {
2    if (n <= 1) return;
3    lib(n - 2);
4    lib(n - 2);
5  };

```

$O(2^n)$ time
 $O(n)$ space

height of $n/2$

- Our Fibonacci function has $O(2^n)$ time complexity and $O(n)$ space complexity

$O(2^n)$ time
 $O(n)$ space

```

1  const fib = (n) => {
2    if (n <= 2) return 1;
3    return fib(n - 1) + fib(n - 2);
4  };

```

Dynamic programming definition

Dynamic Programming

- When we have some larger problem, we can decompose into smaller instances of the same problem. This concept of break down is called **Dynamic Programming**

memoization

- We store duplicate subproblems as we can get those results later on.
- To implement a memoization we pick a fast access data structure
- Usually a HashMap or a JavaScript object
- JavaScript passes data to function by reference

Memoization for Fibonacci

```
int fib(int n){  
    // create a memo  
    static unordered_map<int, int> memo;  
    // find the number  
    auto it = memo.find(n);  
    if(it != memo.end()){  
        return memo[n];  
    }  
  
    if(n <= 2){  
        return 1;  
    }  
  
    // add to the memo  
    memo[n] = fib(n-1) + fib(n-2);  
  
    // return from memo  
    return memo[n];  
}
```

```
const fib = (n, memo = {}) => {
  // check in memo
  if(n in memo) {
    return memo[n];
  }

  if(n <= 2) {
    return 1;
  }

  memo[n] = fib(n-1, memo) + fib(n-2, memo);
  return memo[n];
}

console.log(fib(30));
```

Memoized solution recursion tree

1. Without Memorization

```
1 const fib = (n, memo = {}) => {
2   if (n in memo) return memo[n];
3   if (n <= 2) return 1;
4
5   memo[n] = fib(n - 1, memo) + fib(n - 2, memo);
6   return memo[n];
7 };
```

fib(6)

2. With memoization

```

1 const fib = (n, memo = {}) => {
2   if (n in memo) return memo[n];
3   if (n <= 2) return 1;
4
5   memo[n] = fib(n - 1, memo) + fib(n - 2, memo);
6   return memo[n];
7 };

```

fib(6)

memo

```

{
  3: 2,
  4: 3,
  5: 5,
  6: 8
}

```

- Overall we have roughly $2n$ nodes

$2n$

**fib memoized
complexity
 $O(n)$ time
 $O(n)$ space**

- `Fib(9)` has this structure
- New time complexity is $O(n)$ and space complexity is $O(n)$

Grid Traveller

- You are a traveller on a 2D Grid. You begin in the top-left corner and your goal is to travel to the bottom right corner. You may only move down or right.
- In how many ways can you travel to the goal on a grid with dimensions $m \times n$?
-

gridTraveler(2,3) → 3

1. right, right, down

2. right, down, right

3. down, right, right

- Problems like this.
 - Always start with the smallest possible scenario
 - `gridTraveler(1,1)` → 1 since start is already at end
 - do nothing
 - `gridTraveler(0,1)` → 0
 - invalid
 - `gridTraveler(3,3)`
 -
 - These can be thought of as base cases and can be used to construct the larger solution
- for a `gridTraveler(3,3)`
 - As we move down the problem reduces to `gridTraveler(2,3)`
-

gridTraveler(3,3) → ?

- `gridTraveler(3,3) → ?`

-

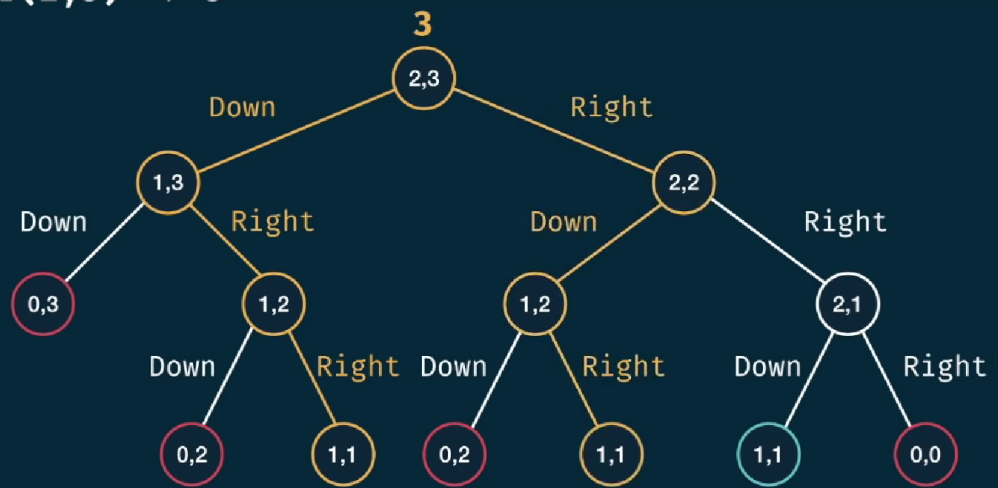

-

- Any problem that looks like recursion always visualize a tree
- At every recursive call we are either reducing by 1 row or by 1 column
- From the tree structure we can already tell which tree nodes were formed by which combination of moves.
- which combination gives a positive answer and which moves lead us to dead end

`gridTraveler(2,3) → 3`

- The tree looks like a binary tree because at every point there are two possible ways to traverse the the grid either down or right
- This tree is now composed of two different factors
- `m` and `n`
- We must take in account the other parameter
-
